                                                                                                                                                                                                                                                                                                                                                                                                                                                  ö
                                                                                                                                                                                     The present sequence is a 5-methyl-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidiane ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes at triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated sproup in the pyrimidine ring. The substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapoutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(3-methyl-1-butpyl) luxacil modified triplex forming oligonocleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance call permetation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                                                                         Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            /*tag= a

                                                                                                                                                                                   The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding double the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at ph 7.0 i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permetation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

                                                                                                    The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-thienyl)-deoxycytidine modified triplex forming oligonuclecties, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding double the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)

The present sequence is a 5-methyl-2'-deoxycytidine/5-methyl-2'-0-
allyluridine modified triplex forming oligonucleotide, comprising
uncleodnomer analogues of cytosine and uridine containing an unsaturated
group in the pyrimidine ring. The 5-substituent provides enhanced binding
capacity in the formation of duplexes and triplexes with single and
double stranded RNA and DNA. Triplexes can be formed at pH 7.0, 1 e.
under physiological pH conditions. The lipophilic groups can also enhance
cell permeation and uptake. The oligomer, which also shows enhanced
nuclease resistance, can be used to form duplexes and triplexes as a
normal oligomer, to inhibit gene expression, e.g. by its antisense
configuration, for therapeutic or research purposes, and for diagnosis by
providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-
2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps

                                                                                                                                                                                                                                                                                                                                                                                                              8
                                                                                                                                                                                                                                                                  ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                              Modification, triplex, duplex, nucleomonomer analogue; unsaturated group; pyrimidine ring, inhibition, gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                       The present sequence is a 5-methyl-2'-O-allyldeoxycytidine modified cytoplace forming alignucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  7
          Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                  Gaps

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomnomer analogues of cytosine and uxidine containing an unsaturated group in the pyrimidine ring. The 5-substituted provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a narmal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    ö

The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-pyridinyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomnomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

Example 18; Col 125-126; 104pp; English.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'-0-allyldeoxyuridine modified triplex forming oligonucleotide, comprising mucleomnomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. can be stranded RNA and DNA. Triplexes can be formed at pB 3.0, i.e. call permeation and uptake. The oligomer, which also shows enhance nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapoutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. Screening of anti-sense oligo:nucleotide(s) for ability to inhibit gene expression - comprises micro-injecting varying amounts of the anti-sense oligomer into a host cell and measuring expression of the target and control genes. WPI; 1998-609233/51.

Example 18; Col 52; 104pp; English.

This sequence represents an antisense oligonucleotide used to test the method of the invention. The method of the invention is for evaluation of an antisense oligomer for its ability to inhibit gene expression, and comprises: microinjecting varying amounts of the antisense oligomer into a host cell along with a target vector for the expression of a gene containing a target sequence for the antisense oligomer and a control vector for the expression of a control gene that encodes a detectable protein and does not contain the target sequence; and measuring expression of the target gene and the control gene. Increasing inhibition of the target gene and the control gene expression, as the amount of antisense oligomer increases indicates the ability of the antisense oligomer increases indicates the ability of the antisense oligomer tho inhibit gene expression. The method is used in oligonucleotide-based therapy and diagnosis. The oligomers have enhanced

Antisense oligonucleotides that down regulate the erbB-2 oncogene -useful to inhibit BRBB2 tyrosine kinase receptor expression in cancer cells to treat epithelial cell, breast, ovarian, lung or colon cancer.

Example 6; Page 15; 31pp; English.

The antisense oligonucleotides AAV40432-V40439 were used to down regulate the erbb-2 oncogene. This oncogene codes for a 185kD tyrosine kinase the erbb-2 oncogene. This oncogene codes for a 185kD tyrosine kinase conversopressed. The oligonucleotides are able to inhibit the overexpressed the oligonucleotides are able to inhibit the conversation of ERBB2 tyrosine kinase receptor in a cell, which can be overexpression of ERBB2 tyrosine kinase receptor in a cell, which can be overexpression of ERBB2 tyrosine kinase receptor in a cell, which can be come by targeting the antisense oligonucleotides to the erbb-2 oncogene. The colloquicleotides were designated the following names, followed by the colloquicleotides were designated the following names, followed by the colloquicleotides were designated the following names, followed by the corrol in the erbb-2 gene that they target: US-1 (151-165); US-1 (151-

single-stranded DNA fragment having a specific nucleic acid sequence in a sample. The method comprises stringently hybridizing a carrier-bonded DNA probe that comprises a single-stranded DNA probe having a carrier-bonded DNA probe that comprises a single-stranded DNA probe having a nucleic acid sequence complementary to the specific nucleic acid sequence of the single-stranded DNA fragment to be detected or quantitatively determined in the sample and a carrier comprising a substance with a very low absorbance for DNA, as bonded together via or without a spacer between them, with DNA fragments in the sample. followed by detecting or carrier-bonded DNA probe. Probes from the present invention are used for detecting point mutations associated with diseases such as cancer. The method is simple and allows very early quantitative diagnoses. The present sequence represents a DNA chain having a K-ras mutant sequence, used in an example from the present invention

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           single-stranded DNA fragment having a specific nucleic acid sequence in a single-stranded DNA fragment having a specific nucleic acid sequence in a sample. The method comprises stringently hybridizing a carrier-bonded DNA probe that comprises a single-stranded DNA probe having a nucleic acid sequence complementary to the specific nucleic acid sequence of the single-stranded DNA fragment to be detected or quantitatively determined in the sample and a carrier comprising a substance with a very low absorbance for DNA, as bonded together via or without a spacer between them, with DNA fragments in the sample, followed by detecting or them, with DNA fragments in the sample, followed by detecting or cuantitatively determining the DNA fragment as hybridised with the carrier-bonded DNA probe. Probes from the present invention are used for detecting point mutations associated with diseases such as cancer. The method is simple and allows very early quantitative diagnoses. The present sequence represents a DNA chain having a K-ras mutant sequence, used in an example from the present invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            .

Assays for target nucleic acid sequences - using a detectable probe and probes for suppressing the binding to a non-target sequence which may be present in a sample.

Example 6; Page 39; 84pp; English.

The invention provides a method for suppressing the binding of a detectable probe to a non-target sequence in an assay of a sample for a target sequence (TS). The method involves (a) contacting the sample with a set containing two or more probes under conditions suitable for the probes to hybridise to nucleic acid, where, at least one of the probes is a detectable moiety and having a sequence complementary to the TS, and at least one of the other probes of the probe having a sequence complementary to a non-TS which may be present in the sample. The method also specifies that atleast one of the present in the sample. The method also specifies that atleast one of the present in the sample by directly or indirectly quantitating the present in the sample by directly or indirectly quantitating the consense of the detectable probe which hybridised to the TS. In the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which differed in the sample base (the wild-type DNA (AAV3323) and the mutant of Sequence by a single base (the wild-type DNA (AAV3323) and the mutant of sequence, such as the present sequence, (see AAV33236 and AAV33241.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The invention provides a method for suppressing the binding of a detectable probe to a non-target sequence in an assay of a sample for a target sequence (TS). The method involves (a) contacting the sample with a set containing two or more probes under conditions suitable for the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    /*tag= b

cc probes to hybridise to nucleic acid, where, at least one of the probes is a detectable wild-type probe labelled with a detectable moiety and having a sequence complementary to the TS, and at least one of the criber probes (also known as a blocker probe) is an unlabelled or independently which may be present in the sample. The method also specifies that atleast one of the labelled probe and the unlabelled probe should be a peptide nucleic acid (PNA) probe. (b) The next step involves detecting the presence or amount of TS present in the sample by directly or indirectly quantitating the cetectable moiety of the detectable probe which hybridised to the TS. In the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which differed in the example given, two passet to the TS. In the example given, two passet to the TS. In the example given, two passet to the WAV33234) which were detected in experimental assays using labelled PNA and DNA probes, such as the present sequence, (see AAV33234) where were performed to examine, compare and quantitate the effects associated with the addition of unlabelled blocker probes, such as the present sequence, (see AAV33236 and AAV33241. The results showed a significant increase in the discrimination of single base changes in target DNA by using the blocker probes. The invention claims that the improves the sensitivity of the assay thereby improving the signal to noise ratio of the assay. Suppression of nonspecific binding of a labelled probe directly improves the sensitivity of the assay thereby improving the signal to costitives and false negative would also be reduced. Using this method, it is claimed that several logs of improvement can be achieved in point of the assay is improvement can be achieved in point of the assay signated on 25-MAR-2003 to correct PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Sequence 15 BP; 4 A; 8 C; 2 G; 1 T; 0 U; 0 Other;

             The specification describes pyrimidinone derivatives. These derivatives are used as labeled binding partners, particularly as labels for diagnostic, analytical and therapeutic applications. The derivatives used as detectable labels for diagnostic assays, to enhance diagnostic assays that use oligonucleotides and to improve potency of also principle oligonucleotides and to improve potency of altering intracellular metabolism of complementary RNA sequences encoding a traget gene. They are also used in transfection complexes to deliver oligonucleotides into cell cyroplasm and in PCR e.g. as primers, and ligase chain reaction (LCR) e.g. as probes. The derivatives have facilitate PCR and LCR processes. The present sequences and target for pyrimidinone derivatives of the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             AAX30947-11815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and

differentially expresent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosting colon or pancreatic cancer in a sample suspected of being neoplastic. The method comparises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Transcript tag sequence increased in pancreatic and colorectal cancer.

The tag sequences can also be used in a method for diagnosting colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Gaps

AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to
                                                                                                                                                                                   AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or the tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can slow be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comparies comparing the level of at least one transcript in a first sample of a tissue to a being neoplastic and the second sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                         Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Use of isolated gene transcripts - useful for developing products for diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Tag sequence, colorectal cancer; pancreatic cancer; colon cancer; diagnosis; prognosis; treatment; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                          AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosting colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                                                                                                                                                                                     Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps

differentially expresent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a being neoplastic and the second sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and ö isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and treatment of cancer. Use of isolated gene transcripts - useful for developing products for diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer. This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probing polymer (PP), at least 1 annealing polymer (AP) and at least 1 set of donor (D) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or product of an present (or product of an present (or product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their geneceptibility to drug increactions. Many different targets can be detected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids.

This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probing polymer (PP), at least 1 annealing polymer (AP) and at least 1 cet of donor (D) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are preticularly used to detect, identify or quantify nucleic acids that are preferred application are closed tube assay, e.g. the product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their geneceptibility to drug interactions. Many different targets can be cheected in a single reaction, using a common (AP) ö Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids. This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probing polymer (PP), at least 1 annealing polymer (AP) and at least 1 ce to fdonor (D) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an preferred applications are detecting viruses and other microorganisms of in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their cystic fibrosis etc.); for analysis/manipulation of plants and their susceptibility to drug interactions. Many different targets can be common (AP)
                                                                                                                                                                                                                                                                                                                                                                          /*tag= a

This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 problemer (PP), at least 1 annealing polywer (PP), the least 1 annealing polywer (PP), at least 1 annealing polywer (PP), and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their succeptibility to drug interactions. Many different targets can be detected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids.
                                                                                                                                                                                                                                                                          Peptide nucleic acid; probing polymer; annealing polymer; detection; identification; virus detection; microorganism; antimicrobial agent; disease; genetic disorder; cancer; thalassemia; cystic fibrosis; ss.

detected in a single reaction, using a common (AP Sequence 15 BP; 4 A; 8 C; 2 G; 1 T; 0 U; 0 Other;

```
This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probing polymer (PP), at least 1 annealing polymer (AP) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an ambification reaction, or present in (living) cells or rissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their succeptibility to drug interactions. Many different targets can be detected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids.
                                                                                                                                                                                                                                                    Peptide nucleic acid; probing polymer; annealing polymer; detection; identification; virus detection; microorganism; antimicrobial agent; disease; genetic disorder; cancer; thalassemia; cystic fibrosis; ss.

capable of modulating a process in a biological system. The method
capable of modulating a process in a biological system. The method
comprises: (a) introducing into the system a random library of nucleic
coid catalysts (NAC) having a substrate binding domain (SBD), comprising
a random sequence, and a catalytic domain (CD); and (b) identifying NAC
in systems where modulation has occurred and/or determining the sequence
of at least part of the SBDs in such systems. Nucleic acid molecules with
endonuclease activity and catalytic activity, from the present invention,
are used to modulate gene expression in plant and mammalian cells and to
cleave target nucleic acid, particularly for treating systemic diseases
caused by specific RNA, e.g. cancer, inflammation, psoriasis, non-hepatic
ascites and infection. They may also be used to detect genetic drift and
acit mitseased cells and to determine c-raf RNA. Specifically NACs
with RNA-cleaving activity that modulate expression of the Raf gene, are
used to treat cancer, restenosis, psoriasis or rheumatoid arthritis, or
generally any condition associated with the level of c-raf. Introduction
of sugar/phosphate modifications increases stability against nuclease and
activity. AAV90922 to AAV93877 repersent NACs that can be used in the
method, specifically for modulating the expression of a Raf gene
                                                                                                                                                                                                                                                                                   Human, c-raf, A-raf, B-raf, hammerhead ribozyme, hairpin ribozyme;

                                                                                                                                                                                                                                               d
                                                                                                                                                                                                                                                                                                           8
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The invention is directed to methods, kits and compositions pertaining to Linear Beacons. It provides novel polymers that comprise at least one linked acceptor moiety where the donor and acceptor moieties are separated by a nucleobase sequence (NBS) and where the polymer form a stem and loop hairpin and is further characterized in that the efficiency of transfer of energy between the donor and acceptor moieties when the polymer is solvated in aqueous solution is independent of at least 2 variables selected from: (a) NBS length; (b) spectral overlap of the donor moiety and the acceptor moiety; (c) presence or absence of magnesium in the aqueous solution; and (d) ionic strength of the aqueous solution. The polymers have a structure such that upon hybridisation to a target sequence the efficiency of energy transfer between the donor and acceptor moieties is altered such that detectable signal from at least one moiety can be used to monitor or quantitate occurrence of the hybridisation event. The polymers can be used to detect organisms in e.g. food, beverages, water, pharmaceutical,

be used to examine clinical samples such as clinical specimens or equipment, fixtures and products such as clinical specimens or equipment, fixtures and products used to treat humans or animals. They can also be used to detect a target sequence which is specific for a genetically based disease or is specific for a predisposition to a genetically based disease, e.g. beta-thalassemia, sickle cell amemia. Pactor-V Leiden, cystic fibrosis and cancer related targets such as p55, p10, BRC-1 and BRC-2. They can also be used to detect a target sequence in a forensic technique such as prenatal screening, paternity testing, identity confirmation or crime investigation. Sequences AAX82052-56 represent DNA probe sequences which are of equivalent subunit length to linear basecons and is used to exemplify the method of the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The invention is directed to methods, kits and compositions pertaining to Linear Beacons. It provides novel polymers that comprise at least one linked donor moiety, at least one linked acceptor moiety where the donor and acceptor moiety at a see separated by a mucleobase sequence (NBS) and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Linear Beacon; polymer; nucleobase sequence; hybridisation; signal; energy transfer; organism detection; pharmaceutical; beta-thalassemis; nucleic acid detection; sickle cell anemia; Factor-V Leiden; cancer; cystic fibrosis; forensic; prenatal screening; paternity testing; probe;

Protection of plants including tomato, pepper, lettuce, radish, parsley, sugar beat, rape, and onions against pathogenic fungi, uses a binucleate thizoctonia strain for biocontrol.

Disclosure; Page 14; 121pp; English

The invention relates to a novel method of protecting plants from pathogenic fungi. The method comprises biocontrol of pathogenic fungi via the uses of a non-pathogenic, binucleates Rhizoctonia is selected by molecular detection of certain binucleate Rhizoctonia is selected by molecular detection of certain internal transcribed spacer (ITS)-5.8s ribosomal DNA sequences (AAZ22445-AAZ22445), which vary between strains of these fungi. The invention also encompasses a concentrate for use in plant protection containing viable material from the binucleate Rhizoctonia strains of the invention, and princes (AAZ22437-22244) for identifying these strains. The strains of the invention are used as biocontrol agents for related pathogenic fungi. Binucleate Rhizoctonia isolate Eab-F2 was tested for its ability to protect tomato seedlings from the pathogenic Rhizocronia strain wee.

Consecutively (the binucleate stain followed by the pathogenic strain), consecutively (the binucleate strain was found to provide protection against the pathogenic strain when it had been allowed to colonise the vegetal surface. The binucleate strain was found to provide protection against the pathogenic strain when it had been allowed to colonise the vegetal surface prior to pathogenic fungal infection [i.e., consecutive consecution effect indicated by protection was provided when both strains were inoculated simultaneously. The method of the invention may be used to brotected include vegetables, crops such as oilseed rape, that may be provided vegetables, crops such as oilseed rape, creliable and provides economical biocontrol of diseases caused by the basis of their ITS sequences AAZ94131-Z92444 represent PCR primers which may be used to identify and distinguish strains of Rhizoctonia on the construint of the pathogenic theory classifying their pathogenicity

Novel ribozymes for th hepatitis C infection.

The present sequence represents the preferred target sequence of an enzymatic nucleic acid, especially a harmerhead ribozyme, which cleaves the Hepatitis C virus (HCV) RNA sequence at the base position given in the descriptor line. The HCV sequence was screened for optimal ribozyme target sites using a computer folding algorithm and regions of the mRNA which did not form secondary folding structures and contained potential ribozyme cleavage sites were identified. Ribozymes were synthesised to target these sites and their activities optimised by either varying the length of the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with hepaticellular carcinoma! The ribozymes may be used in combination with interferon to treat HCV infection, other infectious diseases, autoimmune t C the treatment of diseases and conditions related Claim 1; Page 78; 123pp; English

Novel ribozymes for the treatment of diseases and conditions related to hepatitis C infection.

Claim 1; Page 71; 123pp; English.

The present sequence represents the preferred target sequence of an enzymatic nucleic acid, especially a hammerhead ribozyme, which cleaves conzymatic nucleic acid, especially a hammerhead ribozyme, which cleaves the Heyatitis G virus (HCV) RNA sequence at the base position given in the descriptor line. The HCV sequence was screened for optimal ribozyme carget sites using a computer folding algorithm and regions of the miNA which did not form secondary folding structures and contained potential carget these sites were identified. Ribozymes were synthesised to rarget these sites and their activities optimised by either varying the rarget these sites and their activities optimised by either varying the carget the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with Hepatotis C virus (HCV) infection, e.g. cirrhosse, liver failure and hepatotis C virus (HCV) infection, other infectious diseases, autoimmune interferon to treat HCV infection, other infectious diseases, autoimmune

The present sequence represents the preferred target sequence of an enzymatic nucleic acid, especially a hammerhead ribozyme, which cleaves the Hapatitis C virus (HCV) RNA sequence at the base position given in the descriptor line. The HVV sequence was screened for optimal ribozyme target sites using a computer folding algorithm and regions of the many which did not form secondary folding structures and contained potential ribozyme cleavage sites were identified. Ribozymes were synthesised to target these sites and their activities optimised by either varying the target these sites and their activities optimised by either varying the carget the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with Hepatitis C virus (HCV) infection, e.g. cirrhosis, liver failure and heteron to treat HCV infection, other infectious diseases, autoimmune cancer.
                                                 Enzymatic nucleic acid, hammerhead ribozyme; virus replication; cleavage; cirrhosis; liver failure; hepatocellular carcinoma; interferon; cancer; autoimmune disease; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Novel ribozymes for the treatment of diseases and conditions related to hepatitis C infection.
              Substrate for HH ribozyme HCV-5133 which cleaves HCV RNA at nt.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Query Match 0.5%; Score 10.8; DB 1; Length 15; Best Local Similarity 78.6%; Pred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The present sequence represents the preferred target sequence of an enzymatic nucleic acid, especially a hammerhead ribozyme, which cleaves the Hepatitis C virus (HCV) RNA sequence at the base position given in the descriptor line. The HCV sequence was screened for optimal ribozyme target sites using a computer folding algorithm and regions of the mRNA which did not form secondary folding structures and contained potential ribozyme cleavage sites were identified Ribozymes were synthesised to target these sites and their activities optimised by either varying the carget these sites and their activities optimised by either varying the length of the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with Hepatitis C virus (HCV) infection, e.g. cirrhosis, liver failure and hepatitis continuar carcinoma. The ribozymes may be used in combination with interferon to treat HCV infection, other infectious diseases, autoimmune
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          ö

                                                 The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes. The NR8 family sequences were initially searched for comparison on a nucleic acid database with the nucleic acid probe sequence TGGAGYNNNTGGAGY encoding the amino acid sequence Trp-Ser-Xaa-Trp-Ser. The sequences AAZ59258-Z59300 and AAZ90816-Z90925 represent specific examples of probe sequences used in the search. Antibodies to the NR8 family proteins are used for the diagnosis of blood formation disorders. Compounds identified as binding to the proteins are used for the treatment of such disorders
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes. The NR9 family sequences were initially searched for comparison on a nucleic acid database with the nucleic acid probe sequence TGGAGYNNNTGGAY encoding the amino acid sequence Trp-Ser-Xaa-Trp-Ser. The sequences AAZ59228-Z59300 and AAZ90816-Z9025 represent specific examples of probe sequences used in the search. Antibodies to the NR8 family proteins are used for the diagnosis of blood formation disorders. Compounds identified as binding to the proteins are used for the treatment of such disorders

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               K-ras, electrostatic, polyethylene imine, PEI; bead; matrix, peptide-nucleic acid; PNA; analysis, point mutation; prenatal screening; paternity testing; identity confirmation; crime investigation; ss.
                                                                                                                                         The present sequence is a potential polypurine tract sequence (PPT). The modification of this type of sequence has been shown to optimise the performance of lentiviral vectors. Retroviral based vectors can be used in the gene therapy of many diseases, including cancer, inflammatory diseases such as rheumatoid arthritis and systemic lupus erythematosus, cardiac arrest, myocardial infarction, diseases of the gastrointestinal tract, glandular diseases, renal diseases, dermal diseases, infertility, disease, antoimmune diseases, infertility disease, Alzheimer's disease, Down's syndrome, infectious diseases, and complications due to transplantation or gene therapy
                                              Retroviral vectors with increased titre and transduction ability for use in medicine, especially gene therapy comprises a plus-stranded synthesis
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            /*tag= b

action had been electrostatically bound to polyethylane imine (PEI)
action which had been electrostatically bound to polyethylane imine (PEI)
derivatized beads could be specifically detected using labeled peptide-
nucleic acid (PNA) probes where the labeled (neutral) PNA would not
become immobilized to the beads in the absence of target nucleic acid,
but would hybridze, and therefore become immobilized to the beads, if the
target nucleic acid was present. The DNA templates for PCR were the human
become and a muent K-ras gene, which contains a point mutation at
K-ras gene and a muent K-ras gene, which contains a point mutation at
target nucleic acid sequence which is electrostatically bound to the
matrix and a non-nucleotide probe which specifically hybridiaes to a
portion of one or more target sequences. Immobilized probe/target
complexes can be detected, identified or quantitated under a wide range
of assay conditions. Reversible binding allows the complex to be removed
from the matrix for analysis. The method is rapid, sensitive, reliable
and versatile in detecting target sequences which are particular to
organisms found in fecod, beverages, water and pharmaceutical products.
The non-nucleotide probe/target sequence is protected against degrade
corganisms found in fecod, beverages, water and pharmaceutical products.
The non-nucleotide probe/target sequence is protected against degrade
sample contaminants. The methods, etc. are especially useful for
detection of single point mutations, and hence analysis of a genetically
based disease and in forensic techniques such as prenatal screening,
based disease and in forensic techniques use prenatel screening,
based disease and in forensic techniques as prenatal screening,
based disease and in forensic techniques as prenatal screening,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  ö
                                                            Composition for identifying target sequence of nucleic acids for detecting genetic-diseases and pathogens in food and water, comprises non-nucleotide probe which sequence specifically hybridizes to target
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     K-ras; electrostatic; polyethylene imine; PEI; bead; matrix; peptide-nucleic acid; PNA; analysis; point mutation; prenatal screening; paternity testing; identity confirmation; crime investigation; ss.

AAA AAA29016-26 were used to examine whether the presence of target nucleic acids which had been electrostatically bound to polyethylene imine (PEI) decides which had been electrostatically bound to polyethylene imine (PEI) caid (PNA) probes where the labeled (neutral) PNA would not mucleic acid (PNA) probes where the labeled (neutral) PNA would not become immobilized to the beads in the absence of target nucleic acid, the beam of the prober immobilized to the beads, if the target nucleic acid was present. The DNA templates for PCN were the human K-ras gene and a mutant K-ras gene, which contains a point mutation at the pase 129 (see AAA2907-28). Novel compositions comprise a matrix, a target nucleic acid sequence which is electrostatically bound to the matrix and a non-nucleotide probe which specifically hybridizes to a portion of one or more target sequences. Immobilized probe/target complexes can be detected, identified or quantitated under a wide range of assay conditions. Reversible binding allows the complex to be removed from the matrix for analysis. The method is rapid, sensitive, reliable and versatile in detecting target sequences which are particular to corganisms found in food, beverages, water and pharmaceutical production of single point mutations, and hence analysis of a genetically based disease and in forensic techniques such as prenatal screening, based disease and in forensic techniques such as prenatal screening, beautinty testing, identity confirmation or crime investigation
                                                                                                                                                                                                                                                                                                                                                                                        Composition for identifying target sequence of nucleic acids for detecting genetic-diseases and pathogens in food and water, comprises non-nucleotide probe which sequence specifically hybridizes to target

```

The present sequence is a mutated allele-specific oligonucleotide probe for the G590A mutation in the N-acetyltransferase 2 (NAT2) gene. NAT2 is a xenobiotic-metabolising enzyme. This probe can be used to determine the genotype of an individual at the nat2 locus, and thus determine their susceptibility to toxicity associated with certain drugs, and to certain types of cancer

Oligonucleotide probes hybridizing to genes encoding xenobiotics metabolizing enzymes cytochrome P450 and N-acetyl-transferase 2 (NAT2), useful for detecting genetic polymorphisms.

Simple, rapid and accurate method for distinguishing HLA class I allele type with possibility of mechanization and automation, applicable in judging donor-recipient compatibility during organ transplant and disease diagnosis.

Claim 8; Page 50; 83pp; Japanese

The present invention describes a method for distinguishing a human leukocyte antigen (HLA) class I antigen or allele by a combination of polymerase chain reaction (PCR) using a primer pair whereby all HLA-A, -B or -C alleles can be amplified or using reverse hybridisation analysis comprising a DNA probe covalently bonded to microtitre plate wells which are hybridisable specifically with the base sequence of at least one specific HLA-A, -B or -C allele. The method is applicable in gene typing, judging donor-recipient compatibility during organ transplant and correlation analysis for diagnosis of various diseases. The method is simple, rapid and accurate, with possibility of mechanisation and automation, without the problems encountered by using the prior-art techniques. AAA66943 to AAA67072 represent oligonucleotide probes and PCR primers for use in the method of the present invention

Determining presence or absence of a predetermined endogenous nucleic acid sequence by using an enzyme that depolymenizes the 3' end of an oligonucleotide probe hybridized to a target sequence to release identifier nucleotides.

Example; Page 373; 389pp; English.

The present invention describes a method (MI) for determining the presence or absence of a predetermined endogenous nucleic acid target sequence (ENAT). The method comprises hybridising a probe having an identifier nucleotide (IN) with ENAT which is treated with an enzyme that depolymerises the 3' and of hybridised NA to release the INS. MI is used for determining the number of known sequence repeats present in a nucleic AAA87040

Determining the concentration of a target nucleic acid, useful e.g. for detecting genetic mutations, comprises using a fluorescently labeled probe in which emission is reduced by binding to the target nucleic acid.

Example 7; Page 24; 55pp; English.

The invention relates to the determination of the concentration of a nucleic acid target, using a fluorescently labeled probe which produces creduced fluorescence emission when hybridised to the target nucleic acid. The method comprises measuring the reduction in emission caused by the method comprises measuring the reduction in emission caused by the method comprises produced to the reduction, e.g. for concleic acids by a real-time polymerase chain reaction, e.g. for curcising microbial cells in co-cultures or symbiotic systems, for detecting gene mutations or polymorphisms, and for analysing melting curres of target nucleic acids to determine a Th value. Methods of the convention allow target nucleic acids to be quantified quickly, easily and accurately. Particularly there is no need to remove unbound probe, and no accurately. Particularly there is no need to remove unbound probe, and no accurately. Particularly there is no need to remove unbound probe, and no accurately are introduced that inhibit amplification by Tag polymerase (so conventional PCR conditions can be used). The specificity of PCR is kept of convention is reduced. Complex probes are not needed, and amplification can be used conventionally generated by a computer) has a higher correlation coefficient than conventional graphs so more accurate quantitation is coefficient than conventional graphs so more accurate quantitation is now possible. The current sequence represents a mucleic acid probe of the tonvention that was used for investigating the effects of the kinds of corresponding invention nucleic acid, and the kind of bases in its

The present invention relates to the human uncoupling protein 3 the mitochondrial, proton carrier) (UCP3) gene and polymorphisms. The polymorphisms are associated with obesity, especially diabetes mellitus associated obesity. They polymorphisms may be identified and analysed to determine whether an individual is susceptible to obesity and may be used as the basis for targeted design of drugs to treat obesity. The present sequence was used in the identification and amplification of UCP3
                                                                                                                                                          UCP3; uncoupling protein 3; polymorphism; obesity; diabetes mellitus; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Nucleic acids encoding uncoupling protein 3 (mitochondrial, proton carrier) (UCP3) proteins comprising single nuclectide polymorphisms, useful for the design of drugs for treating obesity.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Human; ml acetylcholine receptor; CHRM1; immunogen; antibody; Alzheimer's disease; dementia with Lewy bodies; DLB; allele specific oligonucleotide probe; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Involves amplifying the nucleic acid sequences in a sample involves amplifying the nucleic acid sample by PCR and then cleaving the amplified products with uracil DNA glycosylase (UDG), the resulting DNA camplified products with uracil DNA glycosylase (UDG), the resulting DNA regiments are detected using reverse blot hybridisation techniques. The method can be used to distinguish between two different sequences, for example for the detection of a DNA fragment carrying a mutation. The method is useful for detection of a DNA fragment carrying a mutation. The squence containing a polymorphic restriction site associated with a diseases such as cystic fibrosis disease, and may be used for detecting infectious diseases. Genetic disorders such as sickle cell anaemia, cystic fibrosis, alpha or beta thalassaemia, muscular dystrophy, and Tay-Sachs disease may also be detected using the method. Oncogenes such as CAS ancers. The present sequence represents a fragment of the cystic fibrosis (CF) gene created by UDG cleavage. This sequence is used in an example of the invention and contains the position of a mutation site in the CF gene. This fragment and the corresponding mutant containing fragment (AAA.72621) can be used to produce probes specifically to intentify the mutation, which can then be used in the method of the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Detecting specific nucleic acid sequence in sample containing nucleic acids involves amplifying nucleic acid, cleaving amplified products with uracil-DNA glycosylase to obtain DNA segments and detecting segments.
                                                                                                                                                                                                                                                                         Uracil DNA glycosylase; UDG; infectious disease detection; cancer; sickle cell anaemia; cystic fibrosis; thalassaemia; muscular dystrophy; Tay-Sachs disease; ss.

The sequence represents an allele specific oligonucleotide probe for acetylcholine receptor. CHMR1. CHMR1 is one subtype of a family of 5 genetylcholine receptor. CHMR1. CHMR1 is one subtype of a family of 5 genetically distinct muscarinic acetylcholine receptors, mAChR, that play important roles in higher brain function such as learning and memory. The protein is a possible drug target for treatments for Alzheimer's disease and antibodies raised against the protein are useful for diagnosing and expression of the gene or activity of the protein, e.g. Alzheimer's disease disease and dementia with Lewy bodies
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   The present invention relates to beta tubulin mutations at positions 214,
                                                                                                                               New variants of the ml muscarinic acetylcholine receptor gene, useful find treatment for Alzheimer's and dementia, have single nucleotide variations at one or more of five polymorphic sites.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Polynucleotide mutations that confers resistance to paclitaxel for detecting paclitaxel-resistant cells in tumor biopsies from patients receiving paclitaxel therapy.
                                                                                                                                                                                                                                                                                                                                                                                                                              ch 0.5%; Score 10.8; DB 1; Length 15; 1 Similarity 85.7%; Pred. The ILIB gene polymorphic variant is useful for therapeutic purposes, for studying the expression and biological function of ILIB, for developing drugs trargeting this protein, and in diagnostics and forensic applications. The method is useful for developing tests and therapeutic treatments for inflammatory and immune disorders. The present sequence is an allelespecific original control of the present sequence is an allele-

Novel polymorphic variant of reference sequence for human cholinergic receptor, muscarinic 3 gene, useful for diagnostic and therapeutic purposes.

Claim 15; Page 19; 54pp; English.

The patent relates to polymorphic variants of human cholinergic receptor, muscarinic 3 (CHRM3) gene. The polymorphic variant comprises at least one single nucleotide polymorphism selected from cytosine at PS1, adenine at PS2 or PS3, and cytosine at PS4. The invention also relates to a method for genotyping and haplotyping the CHRM3 gene for identification of variants. The polymorphic variant is useful for therapeutic purposes, for studying the expression and biological function of CHRM3, as well as for developing drugs targetting the CHRM3 protein. The variant is also useful in diagnostics and forensic applications. The recombinant nonhuman corganism transfected with the polymorphic variant is useful for studying expression of CHRM3 isogenes in vivo, for in vivo screening and testing corganism transfected with the polymorphic variant is useful for studying expression of CHRM3 isogenes in vivo, for in vivo screening and testing the rapeutic agents and compounds for Alzheimer's disease, Sjogren's syndrome, disorders associated with smooth muscle contractility and sudden infant death syndrome. The CHRM3 protein variant is useful in drug creening assays and its antibodies are useful in immunoassays to detect CHRM3 protein variants in biological samples. The present sequence is an allele-specific oligonucleotide (ASO) primer used for detecting human CHRM3 gene polymorphism

New human death-associated protein 6 (DAXX) gene variants comprising 19 polymorphic sites useful in studying the effect of variation on the biological activity of DAXX and in developing drugs targeting the protein.

Claim 15; Page 18; 97pp; English.

Sequences AASG4300-AASG4337 represent oligomucleotide probes specific for a DNA encoding human death-associated protein 6 (DAXX). This DNA may comparise one or more polymorphisms at specific nuclectide positions to comparise one or more polymorphisms at specific nuclectide positions between form one of nineteen possible polymorphic variants. Associations between a trait and a genotype or a haplotype of the DAXX gene can be identified by comparing the frequency of the genotype in a population can exhibiting the trait with that of a reference population. A higher frequency in the trait population indicates an association. Methods involving genotyping or haplotype pairs for the DAXX gene of an individual can lead to prediction of haplotype pairs for the DAXX gene of related individuals, and may be useful in studying the expression and biological individuals, and may be useful in studying the effect of the PAXX are useful in studying the effect of the colymorphic variation on the biological activity of DAXX as well as no the binding affinity of candidate drugs targeting DAXX as well as no the binding cateful for studying population diversity, anthropological lineage, customing the expression and other immune disorders. Polymorphism is also useful for studying population diversity, anthropological lineage, paternity testing, forensic applications, and for identifying containing affinities of one or more candidate drugs targeting the naws to make the DAXX genetic variation and a trait such as level to measure binding affinities of one or more candidate drugs targeting the DAXX protein

Sequences AASO4300-AASO4337 represent oligomuclectide probes specific for a DNA encoding human death-associated protein 6 (DAXX). This DNA may comparise one or more polymorphisms at specific nuclectide postitions to form one of nineteen possible polymorphic variants. Associations between a trait and a genotype or a haplotype of the DAXX gene can be identified by comparing the frequency of the genotype of the population. A higher can be identified by comparing the trait population indicates an association. Methods involving genotyping or haplotype pairs for the DAXX gene of an individual can lead to prediction of haplotype pairs for the DAXX gene of an individual can individuals, and may be useful in studying the expression and biological individuals, and may be useful in studying the effect of the variation on the biological activity of DAXX as well as on the binding affinity of candidate drugs targeting DAXX as well as not be binding affinity of candidate drugs targeting DAXX as well as not be binding affinity of candidate drugs targeting DAXX as well as in a sociations between the DAXX genefic variations of branching population diversity, anthropological lineage, between the DAXX genefic variations and a trait such as level of drug response or susceptibility to disease. DAXX proteins may be used the DAXX can be considered of candidate drugs targeting the more candidate drugs targeting targeting targeting the more candidate drugs targeting target

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGP]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the affects of psoriasis, capable, pityriasis, tuba, pilaris, serborrhoes, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a neovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic brain or skin, discase, higher proliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            ö

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGR]-1 receptor, IGF binding protein [IGFB]-2 or IGFB3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the attisense oligonucleotide of the present invention (see AAF45151 and AAF45153- F45161). The method is usful for ameliorating the effects of psoriasis, inchthyosis, pityriasis, ruba, pilaris, serborthoea, keloids, keratosis, neoplasias, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, the breath of sease, kidney disease, hyperplasia

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisorders. The method comprises contacting the skin with an antisorse oligonucleoride, (for Insulin-like Growth Factor [167]-1 receptor, ISP binding protein [IGPBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, oligonucleoride which can be used to design the antisense oligonucleoride which can be used to design the affects of psoriasis, cligonucleoride of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, richthyosis, pityriasis, ruba, pllaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hypernecvascular condition such as a neovascular condition of the retina, drawn or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Antisense therapy, antiproliferative, antiinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriaals, IGF binding protein; IGFB-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis, serborrhoea, ruba, keratosis; neoplasia; scleroderma, wart; skin cancer; sclerotic disease;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The present invention relates to a method for ameliorating the effects of artisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-F45161). The method is useful for ameliotrating the effects of psoriasis, ichthyosis, pityriasis, tuba, pitaris, serborrhoea, Keloida, keratosis, ichthyosis, pityriasis, unats, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ò

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGR]) receptor, IGF binding protein [IGRBP] - 2 or IGFBB], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153 oligonucleotides of the present invention (see AAF4151 and AAF45153 inhthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, inhthyosis, pityriasis, unda pilaris, serborrhoea, keloids, keratosis, inhthyosis, pityriasis, unda pilaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other scleroic
                                                                                                                                                                                                                                                                                                          Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Sequence 15 BP; 4 A; 2 C; 7 G; 2 T; 0 U; 0 Other;

The present invention relates to a method for ameliorating the effects of shin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [167]) receptor, 107 binding protein [1688]-2 or 16783], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-F45161). The method is useful for ameliocating the effects of psoriasis, ichthyosis, pityriasis, ruba, pliaris, serborrhoea, keloids, keratosis, ichthyosis, pityriasis, ruba, pliaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skii, growth factor-mediated malignancies, other sclerotic vessel or an invention of the inside of blood

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or Example 8; Page 72; 201pp; English inflammation.

WPI; 2001-041421/05.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like drowth Factor [IGFP-1] receptor, IGF binding protein [IGFP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the affects of psoriasis, oligonucleotide which can be used to design the effects of psoriasis, clichnyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperpoliferation of the inside of blood to vessels or any other hyperplasia

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomucleoride, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomucleotide which can be used to design the antisense oligomucleotide which can be used to design the effects of psoriasis, cligomucleotides of the present invention (see AAF45151 and AAF45153-15451). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serbornhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperpoliferation of the inside of blood vessels or any other hyperplasia

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or infiammation.

```
The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF] receptor, IGF binding protein [IGFBP] 2 or IGFBP3), which is capable inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153 and Inthyosis, pityriasis, mub, pitaris, serborrhoea, keloids, keratosis, ichthyosis, pityriasis, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                        vessels or any other hyperplasia

The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [108]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense and oligonuclectides of the present invention (see AAF45151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-8551.) The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperpoliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis, IGF binding protein, IGFBP-2; GPBP3; inflammation, psoriasis; pitaris, growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasis, kidney disease; neobascular condition; hyperplasis, kidney disease;

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 8; Page 93; 201pp; English.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antidense oligomolecuted, (for Insulin-like Growth Factor [IGR]-1 receptor, IGF binding protein [IGREB]-2 or IGFBED), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomolecuties which can be used to design the antisense oligomolecuties of the present invention (see AAF45151 and AAF45153-F4511). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serbornhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a neoplasias, sichney disease, nyperproliferation of the inside of blood disease, kidney disease, hyperproliferation of the inside of blood

The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, inchyosis, pityriasis, ruba, pliaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the Skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antiboration of the form of the state [IGF] -1 receptor, IGF binding protein [IGFBP] -2 or IGFBP], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, coligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153 - CF 45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serbornhea, keloids, keratosis, cohthyosis, soleroderma, warts, benign growths, cancers of the skin, a neopastus condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic condition where the state of the inside of blood

IGF-I oligonucleotide #75

```
Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [IGF]) receptor, IGF binding protein [IGFBP] - 2 or IGFBP], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pliaris, serbornhoea, Keloids, Keratosis, ichthyosis, pityriasis, ruba, pliaris, serbornhoea, Keloids, Keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                    Antisense therapy; antiproliferative; antiinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide; ophthalmological; keloid; skin disorder; Insulin-1ke Growth Factor I receptor; IGF-1; pityriasis; IGF binding procein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilatis; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia; kidney disease; neoplasia; condition; hyperplasia; kidney disease;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           0.5%; Score 10.8; DB 1; Length 15; 85.7%; Pred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide of the present invention (see AAF45151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hypernovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Ameliorating the effects of a disorder, e.g. psoriasis, by administering V (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Gaps

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense eligonucleoride, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFP]-2 or IGFPP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, or inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide is useful for ameliorating the effects of psoriasis, rithyosis, pityriasis, ruba, planis, serborrhoea, keloids, keracosis, neoplasis, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, characteristic series, kidney disease, hyperproliferation of the inside of blood to essels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Antisense therapy, antiproliferative, antiinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide, ophthalmological; keloid; skin disorder; Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding protein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  EXXXXXXXXXXXX
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antidecase oligonucleotide, (for Insulin-like Growth Factor [167]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation.

Inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide of the present invention (see AAF45151 and AAF45153- F45161). The method is useful for ameliorating the effects of psoriasis, cithyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, noplasias, soleroderma, warts, benign growths, cancers of the skin, a hyperpasian or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  ö

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]—1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the effects of psoriasis, cligonucleotide which is useful for ameliorating the effects of psoriasis, rothhyosis, pityriasis, ruba, plaris, serborrhoea, keloids, keratosis, neoplasias, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, chramping and sease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                       Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [108]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide with a present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, chthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keracosis, noplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperproliferation of the inside of blood creating or any other hyperplasia
                                                                                                                                                                                                                                                                                                                             Ameliorating the effects of a disorder, e.g. psoriasis, by administering V (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              .

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomucleotide, (for Insulin-like Growth Factor [IGF]) receptor, IGF binding protein [IGFBP] - 2 r IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomucleotide which can be used to design the antisense oligomucleotides of the present invention (see AAF4151 and AAF45153 oligomucleotides of the present invention (see AAF4151 and AAF45153 inchthyosis, pityriasis, ruba, pliaris, serborrhoea, keloids, keratosis, inchthyosis, pityriasis, ruba, pliaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood

Edmondson SR;

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 8; Page 90; 201pp; English.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [16ff-1] receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation.

CC inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-CC F45161). The method is useful for ameliorating the effects of psoriaais, ichthyosis, pityriasis, ruba, pilaris, serborthoea, keloids, keratosis, colphyparneovascular condition such as a neovascular condition such as a neovascular condition of the retina, by rain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood covered any other hyperpelasia.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, or inhibiting or reducing growth factor mediated cell proliferation, or inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the affects of psoriasis, refs[6]. The method is useful for ameliorating the effects of psoriasis, indeptyosis, pityriasis, ruba, planis, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, the sain or skin, growth factor—mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Antisense therapy, antiproliferative, antiinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological; keloid, skin discorder, insulin-like Growth Factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGFP-1; pityriasis, IGF binding protein, IGFBP-2; IGFBP3; inflammation, psoriasis; pilaris, growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keatosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia; kidney disease; necovascular condition; hyperplasia; kidney disease;
                                                                                                                                                                     oligonucleotides of the present invencion (see ARF45151 and AAF45153-
F5161). The method is useful for ameliorating the effects of postrasis,
ichthyosis, pityriasis, ruba, pilaris, serborthoea, keloids, keratosis,
neoplasias, scleroderma, warts, benign growths, cancers of the skin, a
hyperneovascular condition such as a neovascular condition of the retina,
brain or skin, growth factor-mediated malignancies, other sclerotic
disease, kidney disease, hyperproliferation of the inside of blood
                                              The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contracting the skin with an antisense oligonuclectide, [for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense
                                                                                                                                                                                                                                                                                                                                                                                                      Gaps
                                                                                                                                                                                                                                                                                                                                                                                                        .

The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBPB), which is capable of inhibiting or reducing growth factor mediated cell proliferation,
akin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBF]-2 or IGFBF]-3, which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide which can be used to design the antisense oligonuclectide which can be used to assign the antisense oligonuclectides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, hepplatasis selectoremantal and antiquancies, cancers of the skin, a hyperneovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other selectic disease, hidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin discorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis, IGF binding protein, IGFBP-2; IGFBP3; inflammation, psoriasis, pilaris, growth factor mediated cell proliferation, ichthyosis; serborrhoea; ruba, keratosis, neophasia; scleroderma, wart; skin cancer; sclerotic disease, hypermeovascular condition; hyperplasia, kidney disease; necovascular condition; hyperplasia, kidney disease;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    ô

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The present invention relates to a method for ameliorating the effects of

Example 7; Page 51; 201pp; English.

inflammation.

Antisense therapy; antiproliferative; antinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide; ophthalmological; Keloid; skin discorder; Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding procein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia; kidney disease; neobascular condition of the retina; ss.
inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, Keloids, keratosis, neoplasias, Scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Ameliorating the effects of a disorder, e.g. psorlasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ŏ
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleoride, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleoride which can be used to design the antisense oligonucleotides of the present invention (see AAPA5151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis,

The method comprises contacting the skin with an antiense oligonucleotide, (for Insulin-like Growth Factor [1GF] - receptor, IGF binding protein [IGFBP] - 2 or IGFBPB) which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense of indianation and/or other present invention (see AAF45151 and AAF45153 - 645161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, piryriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding protein, IGFBP-2; IGFBP3; inflammation, psoriasis; pilaris; growth factor mediated cell proliferation, ichthyosis; serborrhoea; ruba, kearcosis; neoplasia; scleroderma, wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperpassa, kidney disease; neovascular condition; hyperpassa, kidney disease;
ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperpoliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                            Gaps

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an anticontection (for Insulin-like Growth Factor [168]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, inchipyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, the brain or skin, growth factor—mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood wessels or any other hyperplasia
                                                                                                                                                                                                                                                             ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Antisense therapy, antiproliferative, antiinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor, IGF-1, pityriasis, IGF binding protein, IGFBP-2, IGFBP3, inflammation, psoriasis, pilatis, growth factor mediated cell proliferation, ichthyosis, serborrhoea, ruba, keratosis, neophasia, scleroderma, wart, skin cancer; sclerotic disease, hyperaneovascular condition, hyperplasia, kidney disease, neovascular condition, hyperplasia, kidney disease,

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [IGF] receptor, IGF binding protein [IGFBP] -2 or IGFBPB, which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide which can be used to design the antisense oligonuclectides of the present invention (see AAF45151 and AAF45153 oligonuclectides of the present invention (see AAF45151 and AAF45153 oligonuclectides of the present invention (see AAF45151 and AAF45153 or pityriasis, ruba, plairs, serborrhoes, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperic condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, hyperproliferation of the inside of blood

```
The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomuclectide, (for Insulin-11ke Growth Factor [107] - receptor, IGF binding protein [IGFBP] - 2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomuclectide which can be used to design the antisense oligomuclectide which can be used to design the antisense oligomuclectides of the present invention (see AAF45151 and AAF45153 - F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, plaris, serborrhoes, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovacular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Antisense therapy, antiproliferative; antinflammatory, antipsoriatic, cytostatic, dermatological; cardiant, virucide, ophthalmological, Keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding procein, IGFBP-2; IGFBP3; inflammation, psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; scaleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia, kidney disease; neovascular condition; hyperplasia; kidney disease;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      0.5%; Score 10.8; DB 1; Length 15;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   The present invention relates to a method for ameliorating the effects of artisense oligonucleotide, (for Invalin-like Growth Factor [IGF] and receptor, IGF binding protein [IGFSP] -2 or IGFBP3), which is capable inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-F5161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

```

The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense Oligonucleotide, (for Insulin-like Growth Factor [IGF] receptor, IGF binding protein [IGFBP] - or IGFBP3, which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153 oligonucleotides of the present invention (see AAF45151 and AAF45153 oligonucleotides of the present invention (see AAF45151 and AAF45153 oligonucleotides of the present invention (see AAF45151 and AAF45153 olichthyosis, pityriasis, ruba, pilaris, serborthoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovacular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood

```

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 6; Page 42; 201pp; English

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, [for Insulin-like Growth Factor [IGP] - ceceptor, IGF binding protein [for Insulin-like Growth Factor [IGP] - ceceptor, IGF binding protein [for Insulin-like Growth Factor [IGF] - ceceptor, IGF binding protein [for Insulin-like Growth Factor [IGF] - ceceptor, IGF binding protein [for Insulin-like Growth is capable of inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the artisense oligonucleotide which can be used to design the artisense oligonucleotide is useful for ameliorating the effects of psoriasis, F45161). The method is useful for ameliorating the effects of psoriasis, cichthyosis, pityriasis, ruba, pilaris, serborrhoes, keloids, keratosis, neoplasias, scleroderma, wats, benign growths, cancers of the skin, a hyperneovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood cessels or any other hyperplasia

IGF-I oligonucleotide #1861. AAF50901 standard; DNA; 15 (first entry) 30-MAR-2001 AAF50901; RESULT 1657

ВР

Antisense therapy, antiproliferative, antiinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis, IGF binding protein, IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris;

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an anticopacification in the skin with an creeptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide of the present invention (see AAF45151 and AAF45153- F45161). The method is useful for ameliorating the effects of psoriasis, cichthyosis, pityriasis, ruba, pilaris, serbortnicea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hypernecvascular condition such as a neovascular condition of the retina, chean in growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperplasia ö Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation. ```
The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomuclectide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomuclectide which can be used to design the antisense oligomuclectides of the present invention (see AAF45151 and AAF45153-4F45161). The method is useful for ameliotacting the effects of psoriesis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovacular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, hyperprovacular condition of the retina, disease, hyperprovacular condition of the retina,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Antisense therapy; antiproliferative; antinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide; ophthalmological; keloid; seth discorder; insulin-like Growth Factor I receptor; IGFP-1; pityriasis; IGF binding protein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neophasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplesia; kidney disease; neovascular condition; hyperplesia; kidney disease;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an artisense oligonuclectide, (for Insulin-IRe Growth Factor [167].

receptor, 1GF binding protein [167BP]-2 or 167BP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide which can be used to design the antisense oligonuclectides of the present invention (see AAF4151 and AAF45153-F4561). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pitaris, serborrhoea, keloids, keratosis, hoppinasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovacular condition uch as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerolic conditions the property of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Antisense therapy; antiproliferative; antiinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide; ophthalmological; keloid; skin discorder; insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding protein; IGFBP-2; IGFBB3; inflammation; psoriasis; pilatis; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; kearcosis; neophasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplamis; kidney disease; neobactic of the retina; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                             Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

(MURD-) MURDOCH CHILDRENS RES INST.

99US-0140345P 21~JUN-1999;

The present invention relates to a method for ameliorating the effects of skin disorders. The method comparises contacting the skin with an antisense oligomucleotide, (for Insulan-like Growth Factor [IGP]) receptor, IGF binding protein [IGFBP] or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, oligomucleotide which can be used to design the antisense oligomucleotides of the present invention (see AAF45151 and AAF45153 oligomucleotides of the present invention (see AAF45151 and AAF45153 idhthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, idhthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or Gaps ö 0.5%; Score 10.8; DB 1; Length 15; 85.7%; Pred.                                                                                                                                                         The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-1ke Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliotrating the effects of psoriasis, ichthyosis, pityriasis, ruba, pitaris, serborrhoea, keloids, keratosis, chophasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a necovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
               Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          .

The present invention relates to a method for ameliorating the effects of antisense origonucleotide, (for Insulan-like Growth Factor [IGP]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide of the present invention (see AAF4151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, inchipyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a neovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin discorder, Insulin-like Growth Factor. I receptor; IGFP-1, pittyriasis, IGF binding procein, IGFB-2, IGFBF3, inflammation, psoriasis, plintis, growth factor mediated cell proliferation, ichthyosis, serborrhoea, ruba, keatoolsis, neoplasia, scleroderma, wart, skin cancer; sclerotic disease, hyperneovascular condition, hyperplasia, kidney disease; neoblasis, condition, hyperplasia, kidney disease;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [GRF]) is receptor, IGF binding protein [GFBP]-2 or IGFBP], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the affects of psoriasis, FASIGI). The method is useful for ameliorating the effects of psoriasis, chthyosis, pityriasis, ruba, pllaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 8; Page 88; 201pp; English.

ō The present invention relates to a method for ameliorating the effects can skin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [IGF] 1 receptor, IGF binding protein [IGFBP] 2 or IGFBP3), which is capable of

ò
inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an objectnucleoride which can be used to design the antisense of objectnucleorides which can be used to design the antisense of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, inhthyosis, pityriasis, thus, pilaris, serborthoea, keloids, keratosis, neoplasis, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, bain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperpoliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin discorder, Insulin-like Growth Factor. I receptor, IGF-1, pityliasis; IGF binding protein, IGFBP-2, IGFBP3, inflammation, psoriasis, pilaris, growth factor mediated cell proliferation, ichthyosis, serborrhoea; ruba, keardosis, neoplasia, scleroderma, wart, skin cancer, sclerotic disease, hyperneovascular condition; hyperplasia, kidney disease; necovascular condition of the retina, ss.
                                                                                                                                                                                                                                                               Gaps

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 6; Page 36; 201pp; English.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomucleotide, (for Insulan-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFB9]-2 or IGFB93), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, oligomucleotide which can be used odesign the antisense oligomucleotide which can be useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serbornhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina,

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligomicleotide, (for Insulin-like Growth Factor [168]-1 receptor, IGF binding protein [1678]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomicleotide which can be used to design the antisense oligomicleotide which can be used to design the AT45151 and AAP45133-0190nucleotide of the present invention (see AAF45151 and AAP45153-1019 prothyosis, pityriasis, rubar, plaris, serborrhoea, keloids, keratosis, inapplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]) receptor, IGF binding protein [IGFBP] 2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-F45161). The method is useful for ameliotating the effects of psoriasis, ichthyosis, pityriasis, ruba, plaris, serborrhoea, keloids, keratosis, ichthyosis, pityriasis, ruba, plaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skih, growth factor-mediated malignancies, other sclaeroic condition such as a neovascular condition of the retina, brain or skih, growth factor-mediated malignancies, other sclaeroic condition such as a neovascular condition such as a neovascular condition such as a neovascular condition of the retina, brain or skih, growth factor-mediated malignancies, other sclaeroic condition such as a neovascular condition of the retina, brain or skih, growth factor-mediated malignancies, other sclaeroic
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [108]-1 receptor, IGF binding protein [formalin-like Growth Factor [108]-1 inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, robthyosis, pityriasis, ruba, plaris, serborrhoea, keloids, keratosis, reoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, chramping sease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1, pittyriasis, IGF binding procein, IGFBP-2, IGFBP3, inflammation, psoriasis, pilaris, growth factor mediated cell proliferation; ichthyosis; serborrhoea, ruba, Keratosis, neophasia; sclaroderma, wart, skin cancer; sclerotic disease, hypermeovascular condition; hyperplasis, kidney disease; necovascular condition of the retina; se.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Gaps

WPI; 2001-041421/05.

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

Example 8; Page 73; 201pp; English.

akin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insuln-1ks Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide which can be used to design the antisense oligonuclectide of the present invention (see AAP45151 and AAP45153-155161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, plaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood The present invention relates to a method for ameliorating the effects of vessels or any other hyperplasia

```

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation is useful for ameliorating the effects of psoriasis, chinyosis, pityriasis, ruba, pitaris, serborrhoea, keloids, keratosis, neoplasis, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperpoliferation of the inside of blood wessels or any other hyperplasia

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]. receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliotating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, hepplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, hyperproliferation of the inside of blood
                                                                                        Antisense therapy, antiproliferative, antiinflammatory, antipsoriatic, cytostatic; dermatological; cardiant; virucide, ophthalmological; keloid; skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding protein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keatosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneowascular condition; hyperplama; kidney disease; neobascular condition; hyperplama; sidney disease;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Gaps

The present sequence is a probe used to detect polymorphisms in the human osteoclastogenesis inhibitory factor (TNFRSF11B). Polymorlectides comprising one or more of twenty four novel single nucleotide polymorphisms in the TNFRSF1B gene have been identified. TNFRSF1B regulate osteoclast recruitment and function. An understanding of rariations in the gene should thus be useful in developing new therapies for metabolic disorders caused by abnormal osteoclast recruitment and function auch as osteoporosis, metaefatic bone disease, Paget's disease, rheumatoid arthritis and periodontal bone disease
                                                                                                                                                                                                                                                                                                                                                                         Human Osteoclastogenesis Inhibitory Factor nucleotides, comprising single nucleotide polymorphisms, useful for studying e.g. osteoporosis, Paget's disease and rheumatoid arthritis.

Human INFRSF11B gene ASO probe, SEQ 1D NO: 67.

ö

Gaps

```
The present sequence is a probe used to detect polymorphisms in the human osteoclastogenesis inhibitory factor (TMFRSF11B). Polymucleorides comprising one or more of twenty four novel single nucleotide polymorphisms in the TMFRSF11B gene have been identified. TMFRSF11B regulate osteoclast recruitment and function. An understanding of variations in the gene should thus be useful in developing new therapies for metabolic disorders caused by abnormal osteoclast recruitment and function such as osteoporosis, metastatic bone disease, Paget's disease, rheumatoid arthritis and periodontal bone disease
